# Water Potability

Is your water safe to drink?

#### Who could use this?

Our stakeholders for this question are generally going to be scientific communities, those interested in studying water quality, government agencies (like the EPA) and potentially private businesses that have stake in making sure water is safe.

### What is "Potability"?

"Potability" is used to describe whether or not water is safe for human consumption. Our goal will be to create a model that is capable of predicting that safety based on the given data.

#### Our Data

- Our data is derived from <u>Kaggle</u>.
- The meta-data on the link above shows this was synthetically generated by: <u>Aditya Kadiwal</u> and is public domain
- This data consists of multiple metrics used for determining the safety of water
- Examples of our data:
  - Solids: The "Total Dissolved Solids" in water such as Potassium, Calcium, and Chlorides
  - **Chloramines:** These are the major disinfectants used in public water. Most commonly formed when Ammonia is added to treat the water.
  - Sulfates: Naturally occurring substances found in minerals, soil, and rocks.
  - Conductivity: Pure water is not a good conductor of electricity. Therefore we study this as a representation of it's impurities.
  - **Organic Carbon:** Organic Carbons are produced from natural decaying material, and some synthetic sources.
  - Among others

#### About our model

Accuracy: 66% False Positives: 11%

- After testing a couple different prediction models, I came to the conclusion that we would use a "KNearestNeighbors"
   model. This model makes predictions, basically, by examining the types of, and how many points are nearest our target.
- Weaknesses: Considering the subject matter, a 66% accuracy is not really something I'd feel comfortable putting into production. Additionally, when dealing with very large amounts of data these types of models can be very slow to make their predictions.

Distribution of our Values by potability ph Solids --- Non Potable Non Potable 0.014 Non Potable Potable Potable Potable 0.012 0.010 € 0.008 0.006 0.004 0.002 0.000 30000 40000 50000 60000 70000 10 14 100 150 200 250 300 350 10000 20000 Hardness Solids Sulfate Chloramines Conductivity - Non Potable Non Potable Non Potable Potable Potable Potable 0.25 0.020 0.004 0.20 0.015 0.003 0.010 0.002 0.10 0.005 0.001 0.05 0.00 0.000 0.000 10 400 500 100 200 400 500 700 800 Sulfate Chloramines Conductivity Organic\_carbon Trihalomethanes Turbidity Non Potable 0.030 Non Potable 0.5 Non Potable 0.12 Potable Potable Potable 0.025 0.10 0.4 0.08 0.020 0.3 o.oe 0.015 0.2 0.04 0.010 0.1 0.02 0.005 0.00 0.000 15 25 30 20 100 120 140 Organic carbon Trihalomethanes Turbidity

## Suggestions for water quality

- I would recommend potentially looking into the materials that we use when transporting our water (Piping, containers, etc.) Based on the increased amount of Sulfates/Solids/Conductivity.
- Look into maybe less usage of Ammonia based cleaners (if possible) based on the amount of Chloramines available in our samples

#### Data Collection Recommendations

This prediction model seems very promising in the respect that it is in its early stages. With more types
of data, like maybe location, date-time data, or even additional data regarding the individual types of
some of our available metrics (for instance sodium or magnesium deposit levels individually) I feel
that it could be a contender, potentially, to be used in real world practice.

## End

Thank you for all of your time! Feel free to send any feedback to: A.cottle1031@gmail.com
